## Introduction to Probability

### Construction of a Probability Space

Objective:

- Define a mathematical framework to describe **random outcomes**
- Enable automated reasoning **under uncertainty**

Example: Coin Toss

- A single toss →unpredictable outcome
- Many tosses →observable pattern in average results

Use mathematics to describe and analyze patterns in random events.

### Frequentist vs. Bayesian Interpretations of Probability

Frequentist Interpretation

- Probability is the **long-run frequency** of an event occurring over repeated trials.
- Defined in the limit as the number of trials goes to infinity.
- Example: "The probability of heads is 0.5" means that in a large number of coin tosses, about half will be heads.

Bayesian Interpretation

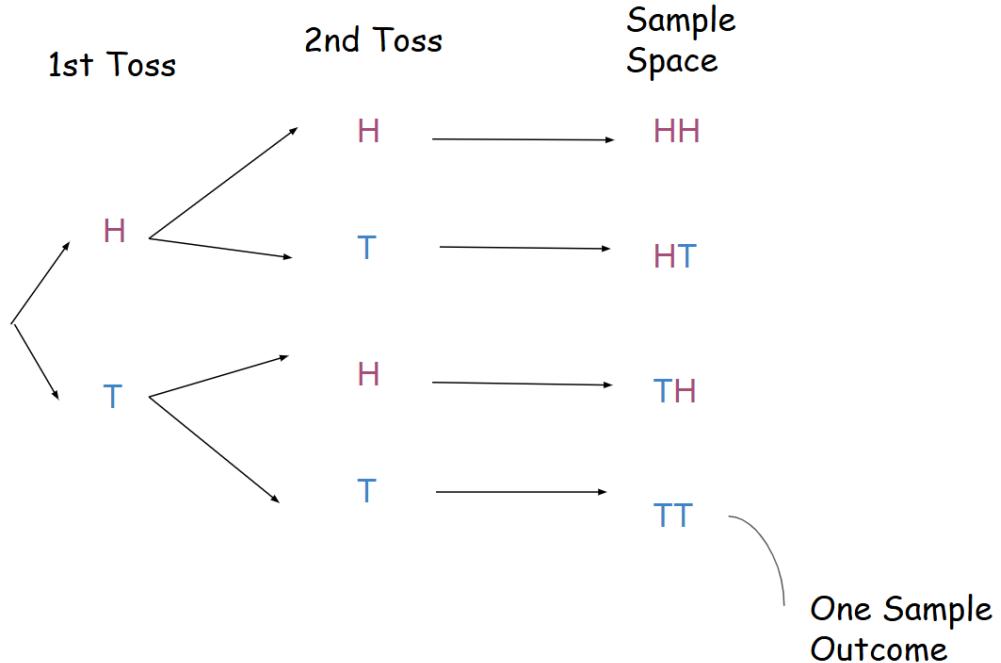

- Probability reflects a **degree of belief** or **uncertainty** about an event.
- Based on **subjective knowledge** it can be **updated** as new information becomes available.
- Example: "I am 80% confident it will rain tomorrow" (based on current data + personal judgment)
- Also called **subjective probability**

### Sample Space

The sample space ( $\Omega$ ), sometimes called the universe, is the set of all possible mutually exclusive outcomes of an event.

$$\Omega_{coin} = \{\text{Heads}, \text{Tails}\}$$

$$\Omega_{twocoins} = \Omega_{coin} \times \Omega_{coin} = \{\langle \text{Heads}, \text{Heads} \rangle, \langle \text{Heads}, \text{Tails} \rangle, \langle \text{Tails}, \text{Heads} \rangle, \langle \text{Tails}, \text{Tails} \rangle\}$$

## Event

A event is a subset of the sample space with some condition. For instance if the event is that the first of two coin tosses is heads.

$$A_{\text{firstheads}} = \{\langle \text{Heads}, \text{Heads} \rangle, \langle \text{Heads}, \text{Tails} \rangle\} \subset \Omega_{\text{twocoins}}$$

We say the probability  $p(A)$  of an event  $A$  is the fraction of all outcomes that  $A$  covers. Therefore, in the example above,  $p(A_{\text{firstheads}}) = \frac{1}{2}$ .

## Event Space

An **event space**,  $\mathcal{A}$ , is the set of all possible events. For discrete events (such as coin flips) this can be thought of typically as the power set of  $\Omega$ .

In continuous spaces it is typically thought of as the Borel field of  $\Omega$  (details of this are beyond the scope of the class for now).

Another way of saying this: consider non-empty  $\Omega$  and  $\mathcal{A}$ :

1.  $A \in \mathcal{A} \rightarrow \bar{A} \in \mathcal{A}$
2.  $A_1, A_2, \dots \in \mathcal{A} \rightarrow \bigcup_{i=1}^{\infty} A_i \in \mathcal{A}$

## Example: Coin Toss

- Sample space ( $\Omega$ ): {Heads, Tails}
- Event space ( $\mathcal{A}$ ): All subsets of  $\Omega$ ,
  - such as:  $\mathcal{A} = \{\emptyset, \{\text{Heads}\}, \{\text{Tails}\}, \{\text{Heads, Tails}\}\}$

### 0.0.1 Example: Rolling a Die

- Sample space ( $\Omega$ ):  $\{1, 2, 3, 4, 5, 6\}$
- Event space ( $\mathcal{A}$ ): All subsets of  $\Omega$ ,
  - such as:  $\mathcal{A} = \{\emptyset, \{1\}, \{2, 4\}, \{1, 2, 3\}, \{1, 3, 5\}, \Omega, \dots\}$

## The Three Axioms

### Axiom 1: Positive Probability

For any event  $A$ ,  $p(A) \geq 0$ .

That is, we cannot have a negative probability. In the previous example, if  $A_{threetails}$  is the event that you get 3 tails when a coin is tossed twice,  $p(A_{threetails}) = 0$ , but this can't be negative.

### Axiom 2: Total Probability

For any sample space,  $\Omega$ ,  $p(\Omega) = 1$ . That is, the probability of something in the sample space happening is 1. So for the example above, the probability of a single coin flip being either Heads or Tails is 1, (as defined), and there are no other possible outcomes.

$$p(\Omega) = p(\text{Head}) + p(\text{Tail}) = 1$$

### Axiom 3: Disjoint Event Space

For disjoint event spaces  $A_1, A_2, \dots, A_n$ ,

$$p(A_1 \cup A_2 \cup \dots \cup A_n) = p(A_1) + p(A_2) + \dots + p(A_n)$$

So in a single coin flip if  $A_{heads}$  and  $A_{tails}$  are the events of a single coin flip being heads and tails respectively, we can see the event spaces are disjoint (they don't share any outcomes).

So,

$$p(A_{heads} \cup A_{tails}) = p(A_{heads}) + p(A_{tails}) = \frac{1}{2} + \frac{1}{2} = 1$$

As a counter example, let's define

$$A_{lastheads} = \{\langle \text{Heads}, \text{Heads} \rangle, \langle \text{Tails}, \text{Heads} \rangle\} \subset \Omega_{twocoins}$$

We can see that

$$p(A_{firstheads} \cup A_{lastheads}) \neq p(A_{firstheads}) + p(A_{lastheads})$$

because  $A_{firstheads} \cap A_{lastheads} = \{\langle \text{Heads}, \text{Heads} \rangle\} \neq \emptyset$ , thus they are not disjoint.

## Interpreting the Axioms

- Axiom 1:  $P(A) \geq 0 \forall A$
- Axiom 2:  $P(\Omega) = 1$
- Axiom 3:  $P(A_1 \cup A_2 \cup \dots \cup A_n) = P(A_1) + \dots + P(A_n)$  for disjoint sets.
